Natural Stone Characteristics:

- The final appearance of the polished surface of each type of granite is determined by the specific components or mix of quartz, feldspars and other material. While the overall appearance will be that of a high gloss finish, some components within the granite may not accept the same level of polish as the rest of the crystals; resulting in so called **dull spots or watermarks.**

Please initial this box if you fully understand the characteristics described above.

- A characteristic referred to as **pitting** my result from granites crystalline structure, which can sometimes result in small spaces that form between the varying mineral crystals. In some instance, certain crystals may also be removed during the polishing process, causing the pits to become more visible. Pitting contributes to the stones uniqueness and will not become worse over the passage of time.

Please initial this box if you fully understand the characteristics described above.

- Granite contains natural **fissures**, which appear as cracks. These are the natural result of the heating and cooling of the stone during its formation million of years ago. Fissures are random and will vary from one type of granite to the next. They will not grow or expand over time.

Please initial this box if you fully understand the characteristics described above.
